

# PRESIDENCY UNIVERSITY

## Laboratory Certificate

This is to certify that Sri Samarth N S Reg No 20201ISB0028  
has satisfactorily completed the course of Experiments in DATA HANDLING  
AND VISUALIZATION Prescribed by the PRESIDENCY UNIVERSITY in the  
Laboratory of this College in the year 2023 - 2024

DATE:.....

Signature of the Lecturer  
in Charge

# INDEX

SI NO.	Name of the Experiment
01	Introduction to Numpy
02	Working to Pandas
03	Data Cleaning
04	Zscore Normalization
05	Outlier Detection with IQR
06	Matplotlib
07	Interacting with Web API
08	Colormaps
09	Heatmaps
10	Seaborn color palette
11	Univariate, Bivariate, Multivariate Visualization
12	Text

axs[1,0].plot(x, np.sin(x+2), color = 'blue')
axs[1,1].plot(x, np.sin(x+4), color = 'green');
```

## □ LABSHEET 2

### □ pandas

```
import pandas as pd
data=pd.read_csv(r'C:\Users\samarth\Downloads\nyc_weather.csv') data.head()
```

	EST	Temperature	DewPoint	Humidity	Sea Level PressureIn	VisibilityMiles	WindSpeedMP
0	1/1/2016	38	23	52	30.03	10	8.
1	1/2/2016	36	18	46	30.02	10	7.
2	1/3/2016	40	21	47	29.86	10	8.
3	1/4/2016	25	9	44	30.05	10	9.

### □ pandas series

```
import numpy as np
d=np.array(['a','b','c','d'])
s=pd.Series(d)
print(s)
```

```
0    a
1    b
2    c
3    d
dtype: object
```

### □ with d being a dictionary

```
d={'a':1.,'b':2,'c':3}
s=pd.Series(d,index=['b','c','d'])
s
```

```
b    2.0
c    3.0
d    NaN
dtype: float64
```

### □ changing the index

```
d=np.array(['a','b','c','d'])
s=pd.Series(d,index=[100,101,102,103])
print(s)
```

```
100    a
101    b
102    c
103    d
dtype: object
```

### □ dtype = float

```
n=np.array([1,2,3])
s1=pd.Series(n,dtype=float)
s1
```

```
0    1.0
1    2.0
2    3.0
```

## syntax

```
pd.Series(data,index=[ ],dtype=, name=, copy=,)
```

## □ combining 2 arrays to make an object

```
a1=np.array([1,2,3])
a2=np.array(['a','b','z'])
s2=pd.Series(a1,a2)
s2
```

```
↔ a    1
   b    2
   z    3
dtype: int32
```

## □ handling missing values

```
d={'a':1., 'b':2, 'c':3}
s=pd.Series(d,index=['b','c','d'])
print(s)
```

```
↔ b    2.0
   c    3.0
   d    NaN
dtype: float64
```

```
s.isna().sum()
```

```
↔ 1
```

```
s.dropna()
```

```
↔ b    2.0
   c    3.0
dtype: float64
```

```
d={'a':1., 'b':2, 'c':3}
s=pd.Series(d,index=['b','c','d'])
print(s)
```

```
↔ b    2.0
   c    3.0
   d    NaN
dtype: float64
```

```
s.fillna(2)
```

```
↔ b    2.0
   c    3.0
   d    2.0
dtype: float64
```

## □ accessing elements from the index

```
series=pd.Series([1,2,3,4,5],index=['a','b','c','d','e'])
series[1]
```

```
↔ 2
```

```
series[:3]
```

```
↔ a    1
   b    2
   c    3
```

```
↔
```

```
series[['a','c','e']]
```

```
a    1
c    3
e    5
dtype: int64
```

```
series1=pd.Series([103,1079,978],index=[' a hundred and three','one thousand seventy nine','nine hundred seventy eight'])
series1['nine hundred seventy eight']
```

```
978
```

DATA FRAME

```
import pandas as pd
data = {'Name':['Alice', 'Bob', 'Claire', 'David'],
        'Age':[20, 21, 20, 22]}
df = pd.DataFrame(data)
print(df)
```

	Name	Age
0	Alice	20
1	Bob	21
2	Claire	20
3	David	22

```
# creating a dataframe from a list of dictionary
data = [{'Name': 'Alice', 'Age': 20},
        {'Name': 'Bob', 'Age': 21},
        {'Name': 'Claire', 'Age': 20},
        {'Name': 'David', 'Age': 22}]
df = pd.DataFrame(data)
print(df)
```

	Name	Age
0	Alice	20
1	Bob	21
2	Claire	20
3	David	22

```
pd.DataFrame(df)
```

	Name	Age
0	Alice	20
1	Bob	21
2	Claire	20
3	David	22

# LABSHEET 3

## Data Cleaning and Data Preprocessing:

1. Data cleaning is the process of changing or eliminating garbage, incorrect, duplicate, corrupted, or incomplete data in a dataset.
2. There's no such absolute way to describe the precise steps in the data cleaning process because the processes may vary from dataset to dataset.

### □ Data Cleaning Cycle

### Missing Values:

```
# import the pandas library
import pandas as pd
import numpy as np

df = pd.DataFrame(np.random.randn(5, 3), index=['a', 'c', 'e', 'f',
'h'], columns=['one', 'two', 'three'])
print(df)
# df = df.reindex(['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h'])

# print (df)
```

```

  one      two      three
a  0.375319 -0.763927 -0.762393
c -1.093644  1.335944 -0.668966
e -0.013401  0.155461 -0.843651
f  0.423813  0.900266 -0.828664
h -0.644593  2.654895  1.211697
```

### Check for Missing Values:

To make detecting missing values easier (and across different array dtypes), Pandas provides the **isnull()** and **notnull()** functions, which are also methods on Series and DataFrame objects –

```
import pandas as pd
import numpy as np

df = pd.DataFrame(np.random.randn(5, 3), index=['a', 'c', 'e', 'f',
'h'], columns=['one', 'two', 'three'])

df = df.reindex(['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h'])

# print (df['one'].isnull())
# print(df)
print(df["one"].isnull())
```

```
→ a    False
   b     True
   c    False
   d     True
   e    False
   f    False
   g     True
   h    False
Name: one, dtype: bool
```

## Replacing the Missing Values

```
#Replace the missing values by 0
import pandas as pd
import numpy as np
df = pd.DataFrame(np.random.randn(3, 3), index=['a', 'c', 'e'], columns=['one',
'two', 'three'])
df = df.reindex(['a', 'b', 'c'])
print (df)
print ("NaN replaced with '0':")
print (df.fillna(0))
```

```
→      one      two      three
a -0.961858 -1.671248  0.556286
b      NaN      NaN      NaN
c -0.386504 -0.709324  0.622838
NaN replaced with '0':
      one      two      three
a -0.961858 -1.671248  0.556286
b  0.000000  0.000000  0.000000
c -0.386504 -0.709324  0.622838
```

## Fill NA Forward and Backward

# Method	Action
pad/ffill	Fill methods Forward
bfill/backfill	Fill methods Backward

```
import pandas as pd
import numpy as np

df = pd.DataFrame(np.random.randn(5, 3), index=['a', 'c', 'e', 'f',
'h'],columns=['one', 'two', 'three'])
df = df.reindex(['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h'])
print(df)
print (df.fillna(method='pad'))
```

	one	two	three
a	0.109813	-1.940379	-0.444834
b	NaN	NaN	NaN
c	-0.208020	0.309864	0.819870
d	NaN	NaN	NaN
e	-0.465764	0.215614	1.031519
f	1.189843	3.814140	0.954030
g	NaN	NaN	NaN
h	0.480653	0.552598	-0.888482

	one	two	three
a	0.109813	-1.940379	-0.444834
b	0.109813	-1.940379	-0.444834
c	-0.208020	0.309864	0.819870
d	-0.208020	0.309864	0.819870
e	-0.465764	0.215614	1.031519
f	1.189843	3.814140	0.954030
g	1.189843	3.814140	0.954030
h	0.480653	0.552598	-0.888482

```
import pandas as pd
import numpy as np

df = pd.DataFrame(np.random.randn(5, 3), index=['a', 'c', 'e', 'f',
'h'],columns=['one', 'two', 'three'])
df = df.reindex(['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h'])

print (df.fillna(method='bfill'))
```

	one	two	three
a	-1.204446	2.137228	-0.388020
b	1.327178	2.355456	-1.347412
c	1.327178	2.355456	-1.347412
d	-0.228600	1.300295	0.939832
e	-0.228600	1.300295	0.939832
f	-0.938383	2.278881	-0.098408
g	0.726762	0.456629	-1.167753
h	0.726762	0.456629	-1.167753

## Drop Missing Values:

Use dropna function along with the axis argument.

By default, axis=0, i.e., along row, which means that if any value within a row is NA then the whole row is excluded.

```
import pandas as pd
import numpy as np

df = pd.DataFrame(np.random.randn(5, 3), index=['a', 'c', 'e', 'f',
'h'], columns=['one', 'two', 'three'])
print(df)
df = df.reindex(['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h'])
print(df)
print (df.dropna())
```

```

      one      two      three
a -0.481989 -1.249458 -2.316982
c  1.119240 -1.054186 -0.972090
e -0.991040 -0.749165  0.259387
f -1.300768 -0.000567 -0.056870
h  0.497341  0.984014 -1.094049
      one      two      three
a -0.481989 -1.249458 -2.316982
b          NaN          NaN          NaN
c  1.119240 -1.054186 -0.972090
d          NaN          NaN          NaN
e -0.991040 -0.749165  0.259387
f -1.300768 -0.000567 -0.056870
g          NaN          NaN          NaN
h  0.497341  0.984014 -1.094049
      one      two      three
a -0.481989 -1.249458 -2.316982
c  1.119240 -1.054186 -0.972090
e -0.991040 -0.749165  0.259387
f -1.300768 -0.000567 -0.056870
h  0.497341  0.984014 -1.094049
```

## Replace Missing (or) Generic Values:

We can achieve this by applying the **replace** method.

Replacing NA with a scalar value is equivalent behavior of the **fillna()** function.

```
import pandas as pd
import numpy as np
df = pd.DataFrame({'one': [10, 20, 30, 40, 50, 2000],
'two': [1000, 0, 30, 40, 50, 60]})
print(df)
print (df.replace({1000:10, 2000:60}))
```

```

      one  two
0      10 1000
1      20    0
2      30   30
3      40   40
4      50   50
5    2000   60
      one  two
0      10   10
1      20    0
```

```
4    50    50
5    60    60
```

## □ Data Preprocessing

1. Load data in Pandas
2. Drop columns that aren't useful
3. Drop rows with missing values
4. Create dummy variables
5. Take care of missing data
6. Convert the data frame to NumPy

**Download Titanic-Dataset from Kaggle.com.**

**Here we are going to use train.csv dataset for preprocessing.**

```
import pandas as pd
import numpy as np
from google.colab import drive
drive.mount('/content/drive')
```

Mounted at /content/drive

```
df = pd.read_csv(r"C:\Users\Thejas Venugopal\Downloads\train (1).csv")
df.info()
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 891 entries, 0 to 890
Data columns (total 12 columns):

dtypes: float64(2), int64(5), object(2)  
memory usage: 55.6+ KB

## Creating Dummy variables

Instead of wasting our data, let's convert the Pclass, Sex and Embarked to columns in Pandas and drop them after conversion.

```
dummies = []  
cols = ['Pclass', 'Sex', 'Embarked']  
for col in cols:  
    dummies.append(pd.get_dummies(df[col]))
```

Transfer the eighth columns

```
titanic_dummies = pd.concat(dummies, axis=1)
```

Concatenate the values with data frame

```
df = pd.concat((df, titanic_dummies), axis=1)
```

Remove the unwanted cols

```
df = df.drop(['Pclass', 'Sex', 'Embarked'], axis=1)
```

## Take care of Missing data

Let's compute a **median or interpolate()** all the ages and fill those missing age values. Pandas has an `interpolate()` function that will replace all the missing NaNs to interpolated values.

# Min Max Scaler and Standardization

**Normalization** is a rescaling of the data from the original range so that all values are within the new range of 0 and 1.

A value is normalized as follows:

$$= (x - \min) / (\max - \min)$$

```
from sklearn.preprocessing import MinMaxScaler
data = [[-1, 2], [-0.5, 6], [0, 10], [1, 18]]
scaler = MinMaxScaler()
print(scaler.fit(data))
MinMaxScaler()
print(scaler.data_max_)
print(scaler.transform(data))
```

```
MinMaxScaler()
[ 1. 18.]
[[0.  0. ]
 [0.25 0.25]
 [0.5  0.5 ]
 [1.   1.  ]]
```

## □ Data Standardization

**Standardizing** a dataset involves rescaling the distribution of values so that the mean of observed values is 0 and the standard deviation is 1.

A value is standardized as follows:

$$y = (x - \text{mean}) / \text{standard\_deviation}$$

Where the mean is calculated as:

$$\text{mean} = \text{sum}(x) / \text{count}(x)$$

And the standard\_deviation is calculated as: standard\_deviation

$$= \sqrt{\text{sum}((x - \text{mean})^2) / \text{count}(x)}$$

```
from numpy import asarray
from sklearn.preprocessing import StandardScaler
# define data
data = asarray([[100, 0.001],
 [8, 0.05],
 [50, 0.005],
 [88, 0.07],
 [4, 0.1]])
print(data)
# define standard scaler
scaler = StandardScaler()
```

```
# transform data  
scaled = scaler.fit transform(data)
```

## LABSHEET 4

```
import numpy as np
import pandas as pd
```

```
# Example dataset
data = {
    'Feature1': [10, 20, 30, 40, 50],
    'Feature2': [5, 15, 25, 35, 45]
}
```

```
# Create a DataFrame
df = pd.DataFrame(data)
```

```
# Display the original data
print("Original Data:")
print(df)
```

```
Original Data:
  Feature1  Feature2
0         10         5
1         20        15
2         30        25
3         40        35
4         50        45
```

```
# Function to normalize data using Z-score
def zscore_normalization(df):
    normalized_df = df.copy()
    for column in normalized_df.columns:
        mean = normalized_df[column].mean()
        std = normalized_df[column].std()
        normalized_df[column] = (normalized_df[column] - mean) / std
    return normalized_df
```

```
# Normalize the DataFrame
normalized_df = zscore_normalization(df)
```

```
# Display the normalized data
print("\nNormalized Data (Z-score):")
print(normalized_df)
```

```
Normalized Data (Z-score):
  Feature1  Feature2
0 -1.264911 -1.264911
1 -0.632456 -0.632456
2  0.000000  0.000000
3  0.632456  0.632456
4  1.264911  1.264911
```

## □ LABSHEET 10

## □ Seaborn Color Palettes

Color is an utmost important aspect of figure styling because it reveals pattern in the data if used effectively; or hide those patterns if used poorly. Even professionals often assume usage of color to portray data as a solved problem. They just pick a palette from a drop-down menu (probably either a grayscale ramp or a rainbow), set start and end points & finally press apply. But it isn't that simple and thus many visualizations fail to represent the underlying data as appropriately as they could.

Primary objective with choice of color is to illuminate datapoints that are concealed in huge datasets.

Quoting Robert Simmon:

Although the basics are straightforward, a number of issues complicate color choices in visualization. Among them: The relationship between the light we see and the colors we perceive is extremely complicated. There are multiple types of data, each suited to a different color scheme. A significant number of people (mostly men), are color blind. Arbitrary color choices can be confusing for viewers unfamiliar with a data set. Light colors on a dark field are perceived differently than dark colors on a bright field, which can complicate some visualization tasks, such as target detection.

One of the most fundamental and important aspects of color selection is the mapping of numbers to colors. This mapping allows us to pseudocolor an image or object based on varying numerical data. By far, the most common color map used in scientific visualization is the rainbow color map. Research paper on [Diverging Color Maps for Scientific Visualization](#) by Kenneth Moreland very well deals with the extended color concepts, if the topic interests you for further analysis.

With all that been said, let us now focus on what Seaborn has to offer BUT before doing that let me once again remind you that Seaborn runs on top of Matplotlib so any color that is supported by [Matplotlib](#) will be supported by Seaborn as well. So at first, let us understand what Matplotlib has to offer:

- ♦ an RGB or RGBA tuple of float values in [0, 1] (e.g., (0.1, 0.2, 0.5) or (0.1, 0.2, 0.5, 0.3))
- ♦ hex RGB or RGBA string (e.g., '#0F0F0F' or '#0F0F0F0F')
- ♦ a string representation of a float value in [0, 1] inclusive for gray level (e.g., '0.5')
- ♦ one of {'b', 'g', 'r', 'c', 'm', 'y', 'k', 'w'}
- ♦ a X11/CSS4 color name
- ♦ a name from the xkcd color survey prefixed with 'xkcd:' (e.g., 'xkcd:sky blue')
- ♦ one of {'C0', 'C1', 'C2', 'C3', 'C4', 'C5', 'C6', 'C7', 'C8', 'C9'}
- ♦ one of {'tab:blue', 'tab:orange', 'tab:green', 'tab:red', 'tab:purple', 'tab:brown', 'tab:pink', 'tab:gray', 'tab:olive', 'tab:cyan'} which are the **Tableau** Colors from the 'T10' categorical palette (which is the default color cycle).

Note that all string specifications of color, other than "CN", are NOT case-sensitive. Let us briefly go through a couple of common supported colors here:

- ♦ RGB/RGBA tuples are 4-tuples where the respective tuple components represent Red, Green, Blue, and Alpha (opacity) values for a color. Each value is a floating point number between 0.0 and 1.0. For example, the tuple (1, 0, 0, 1) represents an opaque red, while (0, 1, 0, 0.5) represents a half transparent green.
- ♦ This is actually another way of representing RGBA codes and common Color Conversion Calculators can be used to translate values. Here is a [Hex to RGBA](#) and [RGB to Hex](#) Color converter for your future assistance.
- ♦ Dictionary of values from {'C0', 'C1', 'C2', 'C3', 'C4', 'C5', 'C6', 'C7', 'C8', 'C9'} represent **Color Quantization**. I have attached a link in the provided notebook that shall guide you to an online book where on Page-29 you could find specifics.

My sole purpose of keeping you posted of Matplotlib background every now and then is only to ensure that when you get to production-level and try to customize a plot as per your analysis, you should know what is ACTUALLY running in the background. This shall empower you to accordingly tweak parameters here and there. Let us now look into few Seaborn options for colors:

```
# Importing required Libraries:
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import seaborn as sns
%matplotlib inline
```

```
# Setting a figure size for all the plots we shall be drawing in this kernel:
sns.set(rc={"figure.figsize": (6, 6)})
```

## □ Building color palettes:

```
current_palette = sns.color_palette()
sns.palplot(current_palette)
```

The most important function for working with discrete color palettes is **color\_palette()**. This function provides an interface to many (though not all) of the possible ways you can generate colors in seaborn, and it's used internally by any function that has a **palette** argument (and in some cases for a **color** argument when multiple colors are needed).

**color\_palette()** will accept the name of any seaborn palette or matplotlib colormap (except **jet**, which you should never use). It can also take a list of colors specified in any valid matplotlib format (RGB tuples, hex color codes, or HTML color names). The return value is always a list of RGB tuples.

Finally, calling **color\_palette()** with no arguments will return the current default color cycle.

```
sns.palplot(sns.color_palette("hls", 8))
```

```
sns.palplot(sns.color_palette("husl", 8))
```

Let me explain these Qualitative (or categorical) palettes. These are best when you want to distinguish discrete chunks of data that do not have an inherent ordering. Ideally, when importing Seaborn, the default color cycle is changed to a set of six colors that evoke the standard matplotlib color cycle. But when we have more than 6, say 8 categories in our data to distinguish, then the most common way is using **hls** color space, which is a simple transformation of RGB values.

Then there is also **hls\_palette()** function that lets you control the lightness and saturation of colors.

All of it displayed above is just the basic Seaborn aesthetics. Let us now look at **xkcd\_rgb** dictionary that has 954 colors in it. Let us try to pull a few out of it:

```
sample_colors = ["windows blue", "amber", "greyish", "faded green", "dusty purple", "pale red",  
sns.palplot(sns.xkcd_palette(sample_colors))
```

Other style is **cubehelix** color palette that makes sequential palettes with a linear increase ordecrease in brightness and some variation in **hue**. Actually let us plot this color palette in a Density contour plot:

```
# Default Matplotlib Cubehelix version:  
sns.palplot(sns.color_palette("cubehelix", 8))
```

```
# Default Seaborn Cubehelix version:  
sns.palplot(sns.cubehelix_palette(8))
```

```
# Density Plot with Seaborn defaults:  
x, y = np.random.multivariate_normal([0, 0], [[1, -.5], [-.5, 1]], size=300).T  
  
sample_cmap = sns.cubehelix_palette(light=1, as_cmap=True)  
sns.kdeplot(x, y, cmap=sample_cmap, shade=True)
```

```

C:\ProgramData\Anaconda3\lib\site-packages\seaborn\_decorators.py:36: FutureWarning:
warnings.warn(
<AxesSubplot:>

```

## □ Interactive widget to create a sequential cubehelix palette:

Let us now play with the parameters to have some fun and choose best parameters:

```
sns.choose_cubehelix_palette(as_cmap=True)
```

```

-----
NameError                                Traceback (most recent call last)
<ipython-input-1-230a1c9055e9> in <cell line: 1>()
----> 1 sns.choose_cubehelix_palette(as_cmap=True)

NameError: name 'sns' is not defined

```

Note that this app only works in this Jupyter Notebook as of now to help choose best parameters for our plot:

```
sns.palplot(sns.cubehelix_palette(n_colors=8, start=1.7, rot=0.2, dark=0, light=.95, reverse=True))
```

start is always between 0 and 3. rot an abbreviation for rotation is kept between -1 and 1. reverse converses the color ordering and hue refers to plot appearance.

## □ Generic Seaborn Plots:

```
# Loading up built-in dataset:  
tips = sns.load_dataset("tips")
```

```
# Creating Strip plot for day-wise revenue:  
sns.stripplot(x="day", y="total_bill", data=tips, color="g")
```

↗ <AxesSubplot:xlabel='day', ylabel='total\_bill'>

This does the job for us but let us try to get better results by plotting each day in different color instead of same color. For this, we shall replace **color** parameter with **palette** parameter:

```
# Set Theme:  
sns.set_style('whitegrid')
```

```
# Creating Strip plot for day-wise revenue:  
sns.swarmplot(x="day", y="total_bill", data=tips, palette="viridis")
```

```
>>> <AxesSubplot:xlabel='day', ylabel='total_bill'>
```

Similarly, let us plot one more and for a change, this time we shall plot a Violin plot:

```
iris = sns.load_dataset("iris")
```

```
sns.boxplot(x="species", y="petal_length", data=iris, palette="cividis")
```

```
>>> <AxesSubplot:xlabel='species', ylabel='petal_length'>
```

There are multiple such palette available for us to play around with like magma, warm grey, gunmetal, dusky blue, cool blue, deep teal, viridian, twilight blue and many more. For customized

color brewing, we may also use color brewer that also offers interesting color palettes for working with Qualitative data. The cool thing about it is that you can use the an interactive Ipython widget function to make the selection of the palette. For this, you only need to use `choose_colorbrewer_palette()` .

There are multiple such palette available for us to play around with like magma, warm grey, gunmetal, dusky blue, cool blue, deep teal, viridian, twilight blue and many more. For customized color brewing, we may also use color brewer that also offers interesting color palettes for working with Qualitative data. A nice feature of the [Color Brewer website](#) is that it provides someguidance on which palettes are color blind safe.

The cool thing about it is that you can use the an interactive Ipython widget function to make theselection of the palette. For this, you only need to use `choose_colorbrewer_palette()` . To access this on your web browser, please access [ColorBrewer](#) link provided in the notebook.

I also found a nice representation of Color Schemes in Seaborn, that I found somewhere on web, so thought of sharing it in your Resource bucket to check out if you wish to. Let's have a look at it

# LABSHEET 11

```
#Installation
#pip install seaborn
```

□  Seaborn2

 Figure

## Figure

It refers to the whole figure that you see. It is possible to have multiple sub-plots (Axes) in the same figure.

## Axes

An Axes refers to the actual plot in the figure. A figure can have multiple Axes but a given Axes can be part of only one figure.

## Axis

An Axis refers to an actual axis (x-axis/y-axis) in a specific plot.

## Four sub-plots (Axes) in a single figure.

 Figure2

## Seaborn

Seaborn - can create complicated plot types from Pandas data with relatively simple commands

Plotting in seaborn is either : Axes-level functions OR Figure-level function

## PLOT CATEGORIES IN SEABORN

**I. Relational plots :** This plot is used to understand the relation between two variables.

**II. Categorical plots:** This plot deals with categorical variables and how they can be visualized.

**III. Distribution plots:** This plot is used for examining univariate and bivariate distributions

**IV. Matrix plots:** A matrix plot is an array of scatterplots.

**V. Regression plots:** The regression plots in seaborn are primarily intended to add a visual guide that helps to emphasize patterns in a dataset during exploratory data analyses.

 Seaborn

```
#Import necessary Packages
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
from matplotlib.pyplot import figure

import seaborn as sns

%matplotlib inline

```
x = np.linspace(0, 10, 1000)  
plt.plot(x, np.sin(x), x, np.cos(x));
```

## # I. Relational Plots

# Line plot : The line plot is one of the most basic plot in seaborn library.

#This plot is mainly used to visualize the data in form of some time series, i.e. in continuous manner.

sns.set(style="dark")

fig, ax = plt.subplots(ncols=2, nrows=1, figsize=(15,10))

#Loading Data with Seaborn

df = sns.load\_dataset("tips")

print(df.head())

#lineplot

sns.lineplot(x="total\_bill", y="tip", hue="size", style="time", data=df,ax=ax[0]).set\_title("Line Plot")

#scatterplot

Sct\_plt=sns.scatterplot(x="total\_bill", y="tip", hue="size", style="time", data=df,ax=ax[1]).set\_title("Scatter Plot")

#Saving Plot

Sct\_plt.figure.savefig('Scatter\_plot1.png')

print('Plot Saved')

```

total_bill  tip    sex smoker  day    time  size
0         16.99  1.01  Female   No  Sun  Dinner    2
1         10.34  1.66   Male   No  Sun  Dinner    3
2         21.01  3.50   Male   No  Sun  Dinner    3
3         23.68  3.31   Male   No  Sun  Dinner    2
4          24.59  3.61  Female   No  Sun  Dinner    4

```

Plot Saved

```
#II. Categorical Plots
#Plots are basically used for visualizing the relationship between variables.
#Variables can be either be completely numerical or a category like a group, class or division.

sns.set_style('darkgrid')
fig, ax =plt.subplots(nrows=5,ncols=2)
fig.set_size_inches(18.5, 10.5)

#Data
# 'tips' dataset contains information about people who probably had food at a restaurant
# whether or not they left a tip for the waiters, their gender, whether they smoke and so on.
df = sns.load_dataset('tips')

#barplot - basically used to aggregate the categorical data according to some methods and by default its the mean
sns.barplot(x='sex', y='total_bill', data = df,palette='plasma', estimator = np.std,ax=ax[0,0]).set_title('Bar Plot')

#countplot -Counts the categories and returns a count of their occurrences
sns.countplot(x='sex', data = df,ax=ax[0,1]).set_title('Count Plot')

#boxplot - known as the box and whisker plot.
#It shows the distribution of the quantitative data that represents the comparisons between variables
sns.boxplot(x='day', y='total_bill', data = df, hue='smoker',ax=ax[1,0]).set_title('Box Plot')

# Similar to the boxplot except that it provides a higher, more advanced visualization
# Uses the kernel density estimation to give a better description about the data distribution.
sns.violinplot(x='day', y='total_bill', data = df, hue='sex', split = True,ax=ax[1,1]).set_title('Violin Plot')

#Stripplot - scatter plot based on the category
sns.stripplot(x='day', y='total_bill', data = df, jitter = True, hue='smoker', dodge = True,ax=ax[2,0]).set_title('Strip Plot')

#Swarmplot-similar to stripplot except the fact that the points are adjusted so that they do not overlap.
sns.swarmplot(x='day', y='total_bill', data = df,ax=ax[2,1]).set_title('Swarm Plot')

#Combining the idea of a violin plot and a stripplot to form this plot
sns.violinplot(x='day', y='total_bill', data = df,ax=ax[3,0])
sns.swarmplot(x='day', y='total_bill', data = df, color='black',ax=ax[3,0]).set_title('Combined Plot')

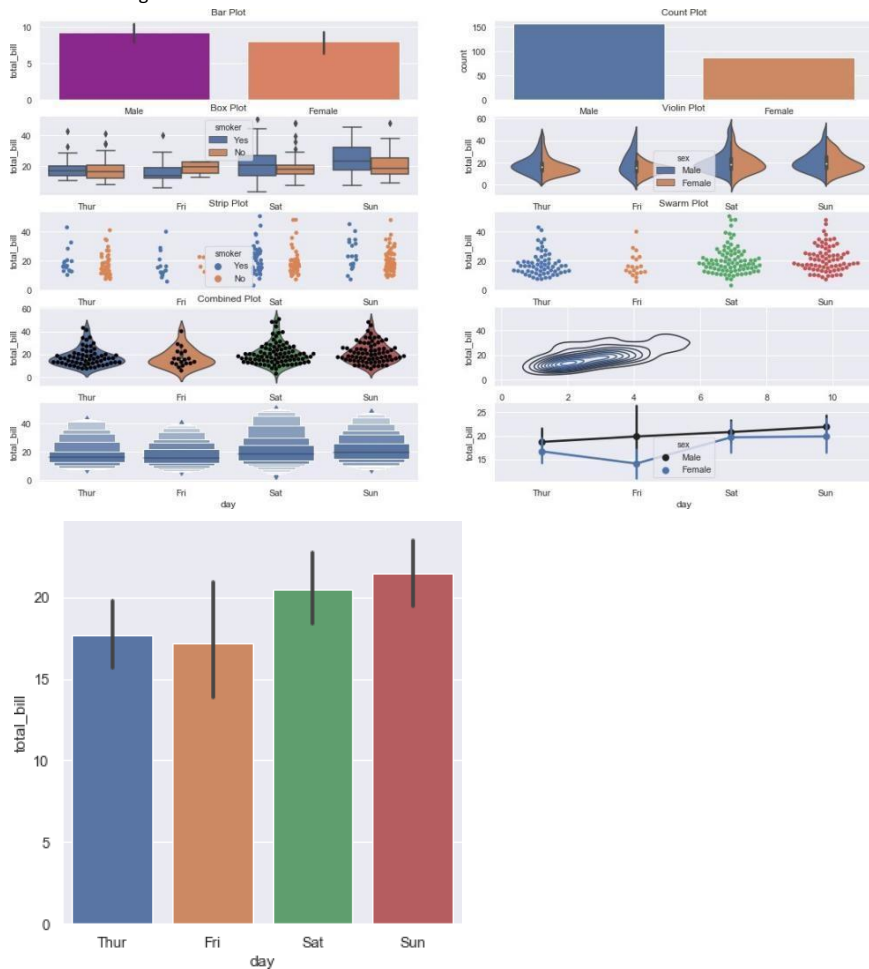

# Density Plot
sns.kdeplot(df['tip'], df['total_bill'],ax=ax[3,1])

#boxenplot
sns.boxenplot(x="day", y="total_bill",color="b", scale="linear", data=df,ax=ax[4,0])

#Ridgeplot
sns.pointplot(x="day", y="total_bill",color="b", hue="sex", data=df,ax=ax[4,1])

#catplot
#General plot - provides a parameter called 'kind' to choose the kind of plot ,better that writing the plots separately.
#The kind parameter can be bar, violin, swarm etc.
sns.catplot(x='day', y='total_bill', data = df, kind='bar')
```

 <seaborn.axisgrid.FacetGrid at 0x1c0d3615888>

III. **Distribution plots** in seaborn is used for examining univariate and bivariate distributions. 4 main types of distribution plots :

```
joinplot
distplot
pairplot
rugplot
```

```
sns.set_style('whitegrid')

#Data - 'iris'
df = sns.load_dataset('iris')
print(df.head())

#Displot- used for univariant set of observations and visualizes it through a histogram
#i.e. only one observation and hence we choose one particular column of the dataset.
#KDE is a way to estimate the probability density function (PDF) of the random variable that “underlies” the sample.
#KDE is a means of data smoothing.
#bins is used to set the number of bins you want in your plot and it actually depends on your dataset.
#color is used to specify the color of the plot
sns.distplot(df['petal_length'], kde = True, color = 'red', bins = 30).set_title('Dist Plot')

#Joinplot/jointgrid- draw a plot of two variables with bivariate and univariate graphs. It basically combines two different plots.
#Plot a bi-variate distribution along with marginal distributions in the same plot
#Joint Distribution of two variables can be visualised using scatter plot/regplot or kdeplot.
#Marginal Distribution of variables can be visualised by histograms and/or kde plot
#KDE shows the density where the points match up the most
#The Axes-level function to use for joint distribution must be passed to JointGrid.plot_joint().
#The Axes-level function to use for marginal distribution must be passed to JointGrid.plot_marginals()

jointgrid = sns.JointGrid(x='petal_length', y='petal_width', data=df)
jointgrid.plot_joint(sns.scatterplot)
jointgrid.plot_marginals(sns.distplot)

#jointplot() to plot bi-variate distribution along with marginal distributions.
#It uses JointGrid() and JointGrid.plot_joint() in the background.
g=sns.jointplot(x = 'petal_length',y = 'petal_width',data = df,kind = 'hex')
g.fig.suptitle('Joint Plot')

#Pairplot- pairwise relation across the entire dataframe
#hue sets up the categorical separation between the entries in the dataset.
#palette is used for designing the plots.
g=sns.pairplot(df, hue ="species", palette ='coolwarm')
g.fig.suptitle("Pair Plot 1")
g.add_legend()

#PairGrid() - creates Axes for each pair of variables
#PairGrid.map() - draws the plot on each Axes using data corresponding to that pair of variables
pairgrid = sns.PairGrid(data=df)
pairgrid = pairgrid.map_offdiag(sns.scatterplot)
pairgrid = pairgrid.map_diag(plt.hist)

#Different kind of plots on Upper Triangular Axes, Diagonal Axes and Lower Triangular Axes.
pairgrid = sns.PairGrid(data=df)
pairgrid = pairgrid.map_upper(sns.scatterplot)
pairgrid = pairgrid.map_diag(plt.hist)
pairgrid = pairgrid.map_lower(sns.kdeplot)

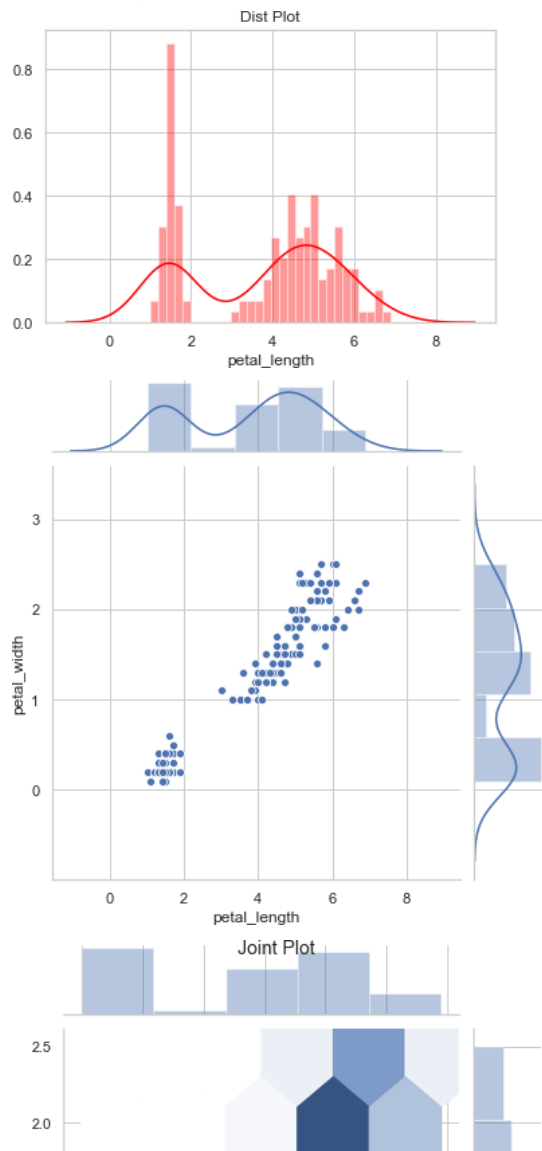

#Avoid Redundancy
g = sns.PairGrid(df, diag_sharey=False, corner=True)
g.map_lower(sns.scatterplot)
g.map_diag(sns.kdeplot)
```

```
sepal_length sepal_width petal_length petal_width species
0          5.1          3.5          1.4          0.2  setosa
1          4.9          3.0          1.4          0.2  setosa
2          4.7          3.2          1.3          0.2  setosa
3          4.6          3.1          1.5          0.2  setosa
4          5.0          3.6          1.4          0.2  setosa
```

```
<seaborn.axisgrid.PairGrid at 0x1c0d2b15888>
```

## LABSHEET 12

### Load the Pacakges

To get started, open a Colab notebook and load the Pandas, Matplotlib, and Wordcloud packages.

```
import pandas as pd
import matplotlib.pyplot as plt
from wordcloud import WordCloud
from wordcloud import STOPWORDS
```

Mount the drive and read the CSV file from the drive.

Here we are going to use netflix\_titles.csv dataset downloaded from kaggle. Since it is text visualization we are going to consider only one column.

```
from google.colab import drive
```

```
drive.mount('/content/drive/')
Mounted at /content/drive/
```

```
df=pd.read_csv('/content/drive/My Drive/Data/netflix_titles.csv', usecols=['cast'])
df.head()
```

	cast
0	NaN
1	Ama Qamata, Khosi Ngema, Gail Mablane, Thaban...
2	Sami Bouajila, Tracy Gotoas, Samuel Jouy, Nabi...
3	NaN
4	Mayur More, Jitendra Kumar, Ranjan Raj, Alam K...

Perform Preprocessing to remove the records containing NaN

```
ndf=df.dropna()
ndf.head()
```

	cast
1	Ama Qamata, Khosi Ngema, Gail Mablane, Thaban...
2	Sami Bouajila, Tracy Gotoas, Samuel Jouy, Nabi...
4	Mayur More, Jitendra Kumar, Ranjan Raj, Alam K...
5	Kate Siegel, Zach Gilford, Hamish Linklater, H...
6	Vanessa Hudgens, Kimiko Glenn, James Marsden, ...

The wordcloud package requires single string instead of column.

Joining the all text data of the coloumn 'cast' to single string to make text visualization easy

```
text = " ".join(item for item in ndf['cast'])
print(text)
```

```
Ama Qamata, Khosi Ngema, Gail Mablane, Thabang Molaba, Dillon Windvogel, Natasha Thahane, Arno Greeff, Xolile Tshabalala, Getmore
```

Sometimes, there will be words in your dataframe that are insignificant and don't add any insight. We can take these out using the STOPWORDS module which is included in Wordcloud.

```
stopwords = set(STOPWORDS)
```

### Create a basic word cloud

The other bits of Matplotlib code turn off the axes and ticks to make the word cloud look a bit neater.

```
plt.figure(figsize=(20,20))
plt.imshow(wordcloud, interpolation='bilinear')
plt.axis("off")
plt.margins(x=0, y=0)
plt.savefig("cloud.jpg", format="jpg")
plt.show()
```

## LABSHEET 13

A time series is the series of data points listed in time order.

A time series is a sequence of successive equal interval points in time.

A time-series analysis consists of methods for analyzing time series data in order to extract meaningful insights and other useful characteristics of data.

For performing time series analysis download stock\_data.csv

```
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
```

```
# reading the dataset using read_csv
df = pd.read_csv(r"stock_data.csv")
# displaying the first five rows of dataset
df.head()
```

	Date	Open	High	Low	Close	Volume	Name
0	1/3/2006	39.69	41.22	38.79	40.91	24232729	AABA
1	1/4/2006	41.22	41.90	40.77	40.97	20553479	AABA
2	1/5/2006	40.93	41.73	40.85	41.53	12829610	AABA
3	1/6/2006	42.88	43.57	42.80	43.21	29422828	AABA
4	1/9/2006	43.10	43.66	42.82	43.42	16268338	AABA

We have used the 'parse\_dates' parameter in the read\_csv function to convert the 'Date' column to the DatetimeIndex format. By default,

Dates are stored in string format which is not the right format for time series data analysis.

Now, removing the unwanted columns from dataframe i.e. 'Unnamed: 0'.

Example 1: Plotting a simple line plot for time series data.

```
df['Volume'].plot()
```

Example 2: Now let's plot all other columns using subplot.

```
array([<AxesSubplot:~>, <AxesSubplot:~>, <AxesSubplot:~>, <AxesSubplot:~>,
      <AxesSubplot:~>], dtype=object)
```

**Resampling:** Resampling is a methodology of economically using a data sample to improve the accuracy and quantify the uncertainty of a population parameter. Resampling for months or weeks and making bar plots is another very simple and widely used method of finding seasonality. Here we are going to make a bar plot of month data for 2016 and 2017.

Example 3:

**Differencing:** Differencing is used to make the difference in values of a specified interval. By default, it's one, we can specify different values for plots. It is the most popular method to remove trends in the data.

```
df.Low.diff(2).plot(figsize=(10, 6))
```

```
df.High.diff(2).plot(figsize=(10, 6))
```

### Plotting the Changes in Data

We can also plot the changes that occurred in data over time. There are a few ways to plot changes in data.

Shift: The shift function can be used to shift the data before or after the specified time interval. We can specify the time, and it will shift the data by one day by default. That means we will get the previous day's data. It is helpful to see previous day data and today's data simultaneously side by side.

```
df['Change'] = df.Close.div(df.Close.shift())  
df['Change'].plot(figsize=(10, 8), fontsize=16)
```

.div() function helps to fill up the missing data values.

Actually, div() means division.

If we take df.div(6) it will divide each element in df by 6.

We do this to avoid the null or missing values that are created by the 'shift()' operation.
